Calculus: Notation

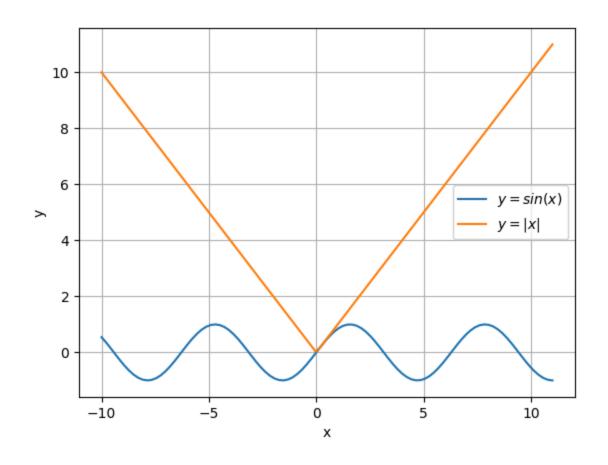

The **derivative** of a function y = f(x) is represented as:

$$f'(x)=rac{dy}{dx}=\lim_{h o 0}rac{f(x+h)-f(x)}{h}$$

The **second derivative** is denoted:

$$f''(x)=rac{d^2y}{dx^2}=rac{d}{dx}igg(rac{dy}{dx}igg)$$

and so on.

Differentiability

For a function to be **differentiable** at a point x_A , it must be:

- **Defined** at x_A
- Continuous at x_A
- Smooth at x_A
- Non-vertical at x_A

Select rules of differentiation

	Function f	Lagrange	Leibniz
Constant	f(x)=c	f'(x) = 0	$\frac{df}{dx} = 0$
Power	$f(x)=x^r$ with $r eq 0$	$f^{\prime}(x)=rx^{r-1}$	$rac{df}{dx} = rx^{r-1}$
Sum	f(x) = g(x) + h(x)	f'(x)=g'(x)+h'(x)	$rac{df}{dx} = rac{dg}{dx} + rac{dh}{dx}$
Exponential	$f(x)=e^x$	$f'(x)=e^x$	$rac{df}{dx}=e^x$
Chain Rule	f(x)=g(h(x))	f'(x)=g'(h(x))h'(x)	$rac{df}{dx} = rac{dg}{dh} rac{dh}{dx}$

Example

1. Find
$$f'(x)$$
 for $f(x)=\sigma(x)=rac{1}{1+e^{-x}}$

2. Now, let, $y=\sigma(x_1)$, where $x_1=wx$. What is $\dfrac{dy}{dx}$?

Partial derivatives

For a scalar valued function $y = f(x_1, x_2)$, there are two partial derivatives:

$$\frac{\partial y}{\partial x_1}, \frac{\partial y}{\partial x_2}$$

These are computed by holding the "other" variable(s) **constant**. For example, if $y=2x_1+x_2+x_1x_2$, then:

$$rac{\partial y}{\partial x_1}=2+x_2, rac{\partial y}{\partial x_2}=1+x_1$$

Linear algebra

Vectors are multidimensional quantities (unlike **scalars**):

$$ec{v} = \mathbf{v} = egin{bmatrix} v_1 \ v_2 \ dots \ v_n \end{bmatrix}$$

A common **vector space** is \mathbb{R}^2 , or the 2D Euclidean plane. Example:

$$\mathbf{v}_1 = egin{bmatrix} 3 \ 4 \end{bmatrix}$$

Vector operations

- Addition: $\mathbf{v}_1+\mathbf{v}_2=egin{bmatrix} v_{11}+v_{21} \ v_{12}+v_{22} \end{bmatrix}$
- Scalar multiplication: $c\mathbf{v} = \begin{bmatrix} cv_1 \\ cv_2 \end{bmatrix}$
- **Dot product**: ${\bf v}_1 \cdot {\bf v}_2 = v_{11} v_{21} + v_{12} v_{22}$ (yields a scalar)
 - Can be thought of as the **projection** of one vector onto another, or how much two vectors are aligned in the same direction

Vector norms

- The **norm** of a vector is a measure of its length
- Most common is the **Euclidean norm** (or L^2 norm):

$$\|\mathbf{v}\|_2 = \|\mathbf{v}\| = \sqrt{\left(\sum_{i=1}^n v_i^2
ight)}$$

ullet You might also see the L^1 norm, particularly as a regularization term:

$$\|\mathbf{v}\|_1 = \sum_{i=1}^n |v_i|$$

Useful vectors

- Unit vector: A vector with a norm of 1, e.g. $\mathbf{x} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$, $\mathbf{y} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$
- Normalized vector: A vector divided by its norm, e.g. $\mathbf{v} = \hat{\mathbf{v}} = \frac{\mathbf{v}}{||\mathbf{v}||}$
- Dot product can also be written as $\mathbf{v}_1 \cdot \mathbf{v}_2 = \|\mathbf{v}_1\| \|\mathbf{v}_2\| \cos(\theta)$

Yes, a normalized vector is also a unit vector, main difference is in context and notation

Matrices

A matrix is a 2D array of numbers:

$$A = egin{bmatrix} a_{11} & a_{12} & a_{13} \ a_{21} & a_{22} & a_{23} \end{bmatrix}$$

Notation: Element a_{ij} is in row i, column j, also written as A_{ij} .

Rows then columns! M imes N matrix has M rows and N columns

Matrix operations

- Addition: element-wise *if* dimensions match. A+B=B+A
- Scalar multiplication: just like vectors
- Matrix multiplication: C=AB where the elements of C are:

$$c_{ij} = \sum_{k=1}^n a_{ik} b_{kj}$$

- \circ Multiply and sum rows of A with columns of B
- \circ Usually, AB
 eq BA

Matrix multiplication examples

Matrix times a matrix:

$$A=egin{bmatrix}2&0\1&3\-4&5\end{bmatrix}, B=egin{bmatrix}-1&0&1\1&3&7\end{bmatrix}$$

Matrix times a vector:

$$A = egin{bmatrix} 0 & -1 \ 1 & 0 \end{bmatrix}, \mathbf{v} = egin{bmatrix} 1 \ 0 \end{bmatrix}$$

Matrix transpose

ullet Transpose: A^T swaps rows and columns

$$A = egin{bmatrix} 1 & 2 \ 3 & 4 \end{bmatrix}, A^T = egin{bmatrix} 1 & 3 \ 2 & 4 \end{bmatrix}$$

• Inverse: just as $\frac{1}{x} \cdot x = 1$, $A^{-1}A = I$, where I is the identity matrix

$$A = egin{bmatrix} 1 & 2 \ 3 & 4 \end{bmatrix}, A^{-1} = egin{bmatrix} -2 & 1 \ 1.5 & -0.5 \end{bmatrix}, A^{-1}A = egin{bmatrix} 1 & 0 \ 0 & 1 \end{bmatrix}$$

Not every matrix is invertible!

A brief introduction to vector calculus

Putting together partial derivatives with vectors and matrices we get:

Scalar-valued $f(\mathbf{x})$:

$$abla f = egin{bmatrix} rac{\partial f}{\partial x_1} \ rac{\partial f}{\partial x_2} \ rac{\partial f}{\partial x_n} \end{bmatrix}$$

Vector-valued f(x):

$$\mathbf{J_f} = egin{bmatrix}
abla^T f_1 \
abla^T f_2 \
\vdots \
abla^T f_m \end{bmatrix} = egin{bmatrix} rac{\partial f_1}{\partial x_1} & \cdots & rac{\partial f_1}{\partial x_n} \
\vdots & \ddots & \vdots \ rac{\partial f_m}{\partial x_1} & \cdots & rac{\partial f_m}{\partial x_n} \end{bmatrix}$$

Most of the time we'll just be working with the gradient

Statistics: Notation

- ullet A **random variable** ${f x}\sim P$ is a variable that can take on random variables according to some probability distribution P
- x may take on **discrete** (e.g. dice rolls) or **continuous** (e.g. age) values
- ullet X or x for the random variable and x or x_i for a specific value
- P(x) for a a discrete distribution and p(x) for continuous
- ullet $\mathbf{x}_P \equiv \mathbf{x} \sim P$ and $\mathbf{x}_p \equiv \mathbf{x} \sim p$

Some textbooks/papers/websites use different notation!

Discrete random variables

- A discrete probability mass function describes the probability of x taking on a specific value
- ullet Example: for a balanced 6-sided die, $P({
 m x}=1)=rac{1}{6}$
- ullet You can add together probabilities, e.g. $P(\mathbf{x} \leq 3) = \sum\limits_{i=1}^3 P(\mathbf{x} = i)$
- ullet $\sum_x P(\mathrm{x}) = 1$ and $P(x_i) \geq 0$ for any valid distribution

Continuous random variables

- A continuous **probability density function** gives the probability of being in some tiny interval δx given by $p(x)\delta x$
- ullet Example: the **uniform distribution**, $p(\mathbf{x}) = rac{1}{b-a}$ for $a \leq x \leq b$
- $p(\mathbf{x} = x_i) = 0$ for any specific value x_i
- Need to integrate to get a concrete value, e.g. $p(\mathrm{x} \leq a) = \int_a^b p(x) dx$
- $\int_{-\infty}^{\infty} p(x) dx = 1$ and $\int_{a}^{b} p(x) dx \geq 0$ for any valid distribution

Expectation and variance

• The **expectation** or **expected value** is its average value $\mathbb{E}[\mathbf{x}]$

$$ullet \mathbb{E}[\mathrm{x}_P] = \sum_x x P(\mathrm{x}) ext{ and } \mathbb{E}[\mathrm{x}_p] = \int_{-\infty}^\infty x p(x) dx$$

• More generally, for any function f(x):

$$\mathbb{E}[f(\mathrm{x})] = \sum_x f(x) P(\mathrm{x}) \quad ext{and} \quad \int_{-\infty}^{\infty} f(x) p(x) dx$$

• The variance describes how much the values vary from their mean:

$$\operatorname{Var}[\mathbf{x}] = \mathbb{E}[(\mathbf{x} - \mathbb{E}[\mathbf{x}])^2]$$

Multiple random variables

- Joint probability P(x,y) is the probability of x and y occurring together
- Conditional probability $P(\mathbf{x}=x\mid \mathbf{y}=y)$ is the probability that \mathbf{x} takes on value x given that $\mathbf{y}=y$ has already happened

$$ullet$$
 In general, $P(\mathrm{x}=x\mid \mathrm{y}=y)=rac{P(\mathrm{x}=x,\mathrm{y}=y)}{P(\mathrm{y}=y)}$

• For independent variables, $P(\mathbf{x} = x \mid \mathbf{y} = y) = P(\mathbf{x} = x)$

Covariance

• The **covariance** between f(x) and g(y) gives a sense of how linearly related they are and how much they vary together:

$$\operatorname{Cov}(f(\mathrm{x}),g(\mathrm{y})) = \mathbb{E}[(f(\mathrm{x}) - \mathbb{E}[f(\mathrm{x})])(g(\mathrm{y}) - \mathbb{E}[g(\mathrm{y})])]$$

- Related to correlation as $\mathrm{Corr}(f(\mathbf{x}),g(\mathbf{y})) = \frac{\mathrm{Cov}(f(\mathbf{x}),g(\mathbf{y}))}{\sqrt{\mathrm{Var}(f(\mathbf{x}))\mathrm{Var}(g(\mathbf{y}))}}$
- The **covariance matrix** of a random vector ${\bf x}$ is a square matrix where the (i,j) element is the covariance between x_i and x_j
- ullet The diagonal of the covariance matrix gives $\mathrm{Var}(x_i)$

The Normal distribution

$$N(x;u,\sigma^2) = \sqrt{rac{1}{2\pi\sigma^2}} \exp^{\left(-rac{1}{2\sigma^2}(x-\mu)^2
ight)}$$

Good "default choice" for two reasons:

- \bullet The **central limit theorem** shows that the sum of many (>30 ish) independent random variables is normally distributed
- Has the most uncertainty of any distribution with the same variance

We can't easily integrate N(x), so numerical approximations are used

Normal Distribution
